Received 25 April 2008/Accepted 28 September 2008

*Escherichia coli* isolates containing the following extended-spectrum beta-lactamases have been detected in 11 of 57 fecal samples (19.3%) in Berlengas Island seagulls: TEM-52 (eight isolates), CTX-M-1 (one isolate), CTX-M-14a (one isolate), and CTX-M-32 (one isolate). Most of the extended-spectrum beta-lactamase-positive isolates harbored class 1 or class 2 integrons, which included different antibiotic resistance gene cassettes.

The emergence and wide dissemination of extended-spectrum beta-lactamases (ESBLs) among clinical *Escherichia coli* isolates in hospitals in recent years are of great concern and represent a problem for the treatment of infectious diseases (19). It has also been reported that *E. coli* isolates containing ESBLs, mostly of the CTX-M class, are frequently detected in community patients (4) and have also been found in food-producing animals and household pets (2, 3, 5, 8, 11, 14, 17, 24). Moreover, a previous report identified ESBLs in fecal *E. coli* isolates of wild animals (9), mainly in birds of prey, but seagulls were not included in that study. ESBLs seem to be widely distributed in bacteria of different ecosystems, although more information is needed, especially for wild ecosystems. The purpose of our study was to analyze the carriage of ESBL-containing *E. coli* isolates in fecal samples of Berlengas Island seagulls and also to characterize the type of ESBLs and the phylogenetic groups of isolates. Berlengas Island is part of the Berlangas Natural Reserve, located 5.7 miles from the Portuguese coast, and it belongs to the National Network of Protected Areas. Fishermen inhabited the island in the past, but currently nobody lives there year round, although some tourists visit the island and a few people stay for vacations. Diverse species of seagulls make their nests on this island; in the last few years the population of seagulls has increased significantly and is considered a true plague (18).

Fifty-seven fresh seagull fecal droppings were obtained in different areas of the Berlengas Island during September 2007 and were tested for the presence of ESBL-containing *E. coli* isolates. Fecal samples were seeded in Levine agar plates supplemented with cefotaxime (CTX; 2 µg/ml), and colonies with typical *E. coli* morphology were selected and identified by classical biochemical methods and by the API 20E system (bioMérieux, La Balme Les Grottes, France). Susceptibility of the recovered *E. coli* isolates to 16 antibiotics (ampicillin, amoxicillin plus clavulanic acid, cefoxitin, CTX, ceftazidime, aztreonam, imipenem, gentamicin, amikacin, tobramycin, streptomycin, nalidixic acid, ciprofloxacin, sulfamethoxazole–trimethoprim, tetracycline, and chloramphenicol) was tested by the disk diffusion method (7). *E. coli* ATCC 25922 was used as a quality control strain. Broad-spectrum cephalosporin-resistant isolates were selected for further studies (one isolate per sample), and they were screened for ESBL production according to the CLSI criteria (7).

The presence of genes encoding TEM, SHV, OXA, CTX-M, and CMY type beta-lactamases was studied by specific PCRs (1, 13, 23). All obtainedamplicons were sequenced on both strands, and sequences were compared with those included in the GenBank database and in the website http://www.lahey.org/Studies/ to identify the beta-lactamase genes. The genetic environment of *bla*<sub>CTX-M</sub> genes was also tested by PCR and by sequencing with previously reported primers (10, 15, 22).

The presence of other antibiotic resistance genes, associated with chloramphenicol (*cmIa*), tetracycline (*tetA* and *tetB*), streptomycin (*aadA*), and sulfonamide (*sul1*, *sul2*, and *sul3*) resistance, among our isolates was also analyzed by PCR and sequencing (21). The presence of the *intI1* and *intI2* genes, encoding class 1 and 2 integrases, respectively, and the composition of the variable regions of class 1 and 2 integrons were studied by PCR and sequencing (21). The identification of the major phylogenetic groups among our isolates was determined by PCR (6). Positive and negative controls from the bacterial collection of the University of La Rioja, Logroño, Spain, were used in all assays.

*E. coli* isolates were detected in Levine CTX plates from 11 of the 57 (19.3%) fecal samples studied. All 11 isolates obtained from these samples were intermediate or resistant to CTX and/or ceftazidime and had a positive screening test for ESBL production. Only 1 of the 11 *E. coli* isolates (GV-
10) showed resistance to amoxicillin plus clavulanic acid. The beta-lactamase genes detected in these isolates were the following (numbers of isolates are in parentheses): \( \text{bla}\text{TEM-52} \) (8), \( \text{bla}\text{CTX-M-1} \) plus \( \text{bla}\text{OXA-1} \) (1), \( \text{bla}\text{CTX-M-14a} \) (1), and \( \text{bla}\text{CTX-M-32} \) (1) (Table 1). It is interesting that 73% of the ESBL-positive isolates of seagulls harbored the \( \text{bla}\text{TEM-52} \) gene and that 27% of the isolates harbored the \( \text{bla}\text{CTX-M} \) gene. A high prevalence of TEM-52 has also been recently observed in \( \text{E. coli} \) isolates from healthy food-producing animals and chicken meat products from Portugal (16).

Different genetic environments surrounding the \( \text{bla}\text{CTX-M} \) genes were detected (Fig. 1). The sequence of the fragment obtained by PCR upstream of the \( \text{bla}\text{CTX-M-1} \) gene in the \( \text{E. coli} \) GV-23 strain revealed the presence of a region of the IS26 transposase flanking a partially truncated \( \text{ISEcp1} \) followed by an intergenic region; this whole structure has been previously found in \( \text{E. coli} \) (13, 22). The presence of \( \text{ISEcp1} \) and \( \text{IS}903 \) surrounding the \( \text{bla}\text{CTX-M-14a} \) gene in \( \text{E. coli} \) GV-10 was identified, and the genetic environment of the \( \text{bla}\text{CTX-M-32} \) gene detected in \( \text{E. coli} \) GV-12 included \( \text{ISEcp1}/\text{IS}5 \) upstream of the \( \text{bla} \) gene and \( \text{orf}477 \) downstream, as also detected by others (25).

\(^b\) The \( \text{qacE}+\text{plus-sul1} \) conserved region was absent in two \( \text{intI1} \)-positive \( \text{E. coli} \) isolates containing \( \text{bla}_{\text{TEM-52}} \) and \( \text{bla}_{\text{CTX-M-32}} \).

FIG. 1. Genetic environment of \( \text{bla}_{\text{CTX-M}} \) genes in three \( \text{E. coli} \) isolates recovered from seagull fecal samples (the intergenic X, Y, and W regions have been previously reported [10]).
A variety of resistance genes (cmlA, tetA, tetB, adaA, sul1, sul2, and sul3) were observed among our ESBL-producing *E. coli* isolates (Table 1). Five isolates harbored class 1 integrons with the following gene cassettes in their variable regions: dfrA1 plus adaA1 (two isolates), sat plus psp plus adaA2 (one isolate), sat plus adaA1 (1 isolate), and bls-OXA-1 plus adaA1 (1 isolate). Five isolates harbored class 2 integrons, and the gene cassette arrangement dfrE1 plus sat plus adaA1 was identified in all of them. *E. coli* GV-8 contained simultaneously class 1 and 2 integrons. Eight of the ESBL-positive isolates corresponded to the A phylogenetic group, two isolates corresponded to the D group, and only one bls-TEM-52 isolate was assigned to the B2 phylogenetic group (Table 1). Previous studies have reported the association of *E. coli* isolates of the B2 group with extraintestinal infections (20), and the fecal origin of our isolates could explain the low prevalence of this phylogroup.

It is important to note the high prevalence and moderate diversity of ESBLs detected in fecal *E. coli* from seagulls that inhabit a natural reserve, as is the case for Berlengas Island. As previously indicated, the population of seagulls on an island that is not too far away from the Portuguese coast has significantly increased in recent years. The possibility that these animals eat the remains of human food cannot be excluded. This study gives new evidence for the wide dissemination of ESBLs in *E. coli* isolates from wild animals, as is the case for seagulls. More studies of this nature should be performed in the future to analyze the prevalence of this type of resistant bacteria in different ecosystems.

This work was partly financed by project SAF2006-14207-C02 of the Ministry of Science and Education of Spain. We also thank Pfizer for partial financial support. L. Vinué was supported by a fellowship from the Spanish Ministry of Education and Science (SAF2006-14207-C02-01), and S. Somalo was supported by a fellowship from the Government of La Rioja, Spain (Colabora 2007/15).
